k-Nearest Neighbor (kNN) exercise

Complete and hand in this completed worksheet (including its outputs and any supporting code outside of the worksheet) with your assignment submission. For more details see the [assignments page (https://compsci682-fa19.github.io/assignments2019/assignment1)](https://compsci682-fa19.github.io/assignments2019/assignment1) on the course website.

The kNN classifier consists of two stages:

- During training, the classifier takes the training data and simply remembers it
- During testing, kNN classifies every test image by comparing to all training images and transfering the labels of the k most similar training examples
- The value of k is cross-validated

In this exercise you will implement these steps and understand the basic Image Classification pipeline, cross-validation, and gain proficiency in writing efficient, vectorized code.

```
# Run some setup code for this notebook.
from __future__ import print_function

import random
import numpy as np
from cs682.data_utils import load_CIFAR10
import matplotlib.pyplot as plt

# This is a bit of magic to make matplotlib figures appear inline in the
notebook
# rather than in a new window.
%matplotlib inline
plt.rcParams['figure.figsize'] = (10.0, 8.0) # set default size of plots
plt.rcParams['image.interpolation'] = 'nearest'
plt.rcParams['image.cmap'] = 'gray'

# Some more magic so that the notebook will reload external python modul
es;
# see http://stackoverflow.com/questions/1907993/autoreload-of-modules-i
n-ipython
%load_ext autoreload
%autoreload 2
```

In [2]:
```
# Load the raw CIFAR-10 data.
cifar10_dir = 'cs682/datasets/cifar-10-batches-py'

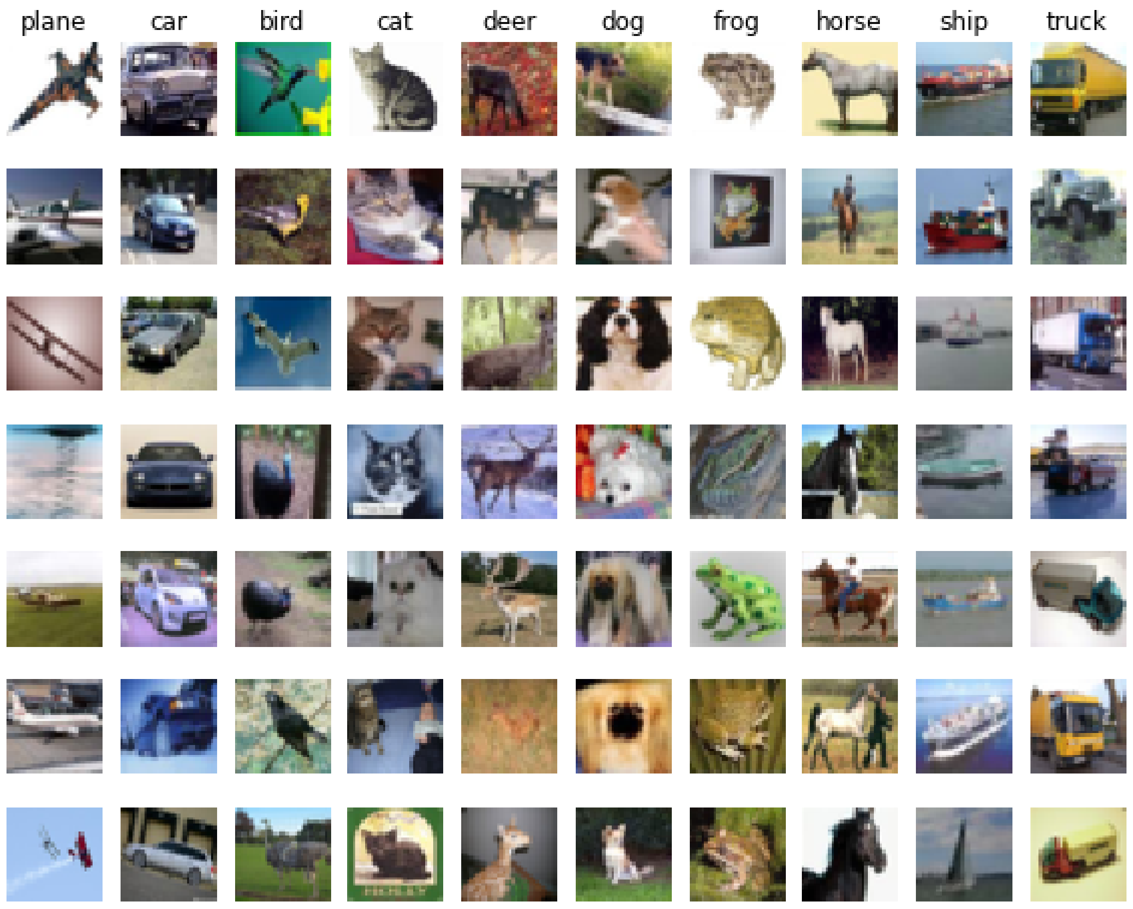
# Cleaning up variables to prevent loading data multiple times (which ma
y cause memory issue)
try:
   del X_train, y_train
   del X_test, y_test
   print('Clear previously loaded data.')
except:
   pass

X_train, y_train, X_test, y_test = load_CIFAR10(cifar10_dir)

# As a sanity check, we print out the size of the training and test dat
a.
print('Training data shape: ', X_train.shape)
print('Training labels shape: ', y_train.shape)
print('Test data shape: ', X_test.shape)
print('Test labels shape: ', y_test.shape)
```

```
Training data shape:  (50000, 32, 32, 3)
Training labels shape:  (50000,)
Test data shape:  (10000, 32, 32, 3)
Test labels shape:  (10000,)
```

In [3]:
```
# Visualize some examples from the dataset.
# We show a few examples of training images from each class.
classes = ['plane', 'car', 'bird', 'cat', 'deer', 'dog', 'frog', 'horse'
, 'ship', 'truck']
num_classes = len(classes)
samples_per_class = 7
for y, cls in enumerate(classes):
    idxs = np.flatnonzero(y_train == y)
    idxs = np.random.choice(idxs, samples_per_class, replace=False)
    for i, idx in enumerate(idxs):
        plt_idx = i * num_classes + y + 1
        plt.subplot(samples_per_class, num_classes, plt_idx)
        plt.imshow(X_train[idx].astype('uint8'))
        plt.axis('off')
        if i == 0:
            plt.title(cls)
plt.show()
```



In [4]:
```
# Subsample the data for more efficient code execution in this exercise
num_training = 5000
mask = list(range(num_training))
X_train = X_train[mask]
y_train = y_train[mask]

num_test = 500
mask = list(range(num_test))
X_test = X_test[mask]
y_test = y_test[mask]
```

In [5]:
```
# Reshape the image data into rows
X_train = np.reshape(X_train, (X_train.shape[0], -1))
X_test = np.reshape(X_test, (X_test.shape[0], -1))
print(X_train.shape, X_test.shape)
```

```
(5000, 3072) (500, 3072)
```

In [6]:
```
from cs682.classifiers import KNearestNeighbor

# Create a kNN classifier instance.
# Remember that training a kNN classifier is a noop:
# the Classifier simply remembers the data and does no further processin
g
classifier = KNearestNeighbor()
classifier.train(X_train, y_train)
```

We would now like to classify the test data with the kNN classifier. Recall that we can break down this process into two steps:

1. First we must compute the distances between all test examples and all train examples.
2. Given these distances, for each test example we find the k nearest examples and have them vote for the label

Lets begin with computing the distance matrix between all training and test examples. For example, if there are **Ntr** training examples and **Nte** test examples, this stage should result in a **Nte x Ntr** matrix where each element (i,j) is the distance between the i-th test and j-th train example.

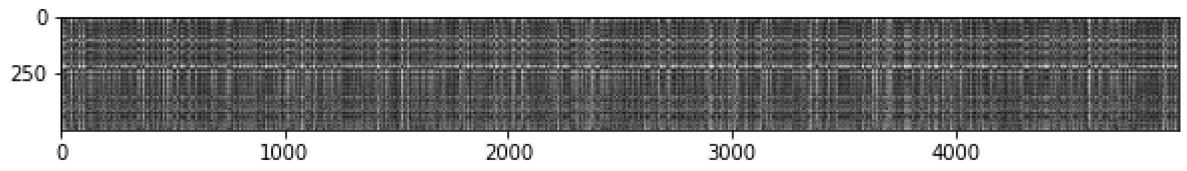
First, open `cs682/classifiers/k_nearest_neighbor.py` and implement the function `compute_distances_two_loops` that uses a (very inefficient) double loop over all pairs of (test, train) examples and computes the distance matrix one element at a time.

In [7]:
```
# Open cs682/classifiers/k_nearest_neighbor.py and implement
# compute_distances_two_loops.

# Test your implementation:
dists = classifier.compute_distances_two_loops(X_test)
print(dists.shape)
```

```
(500, 5000)
```

In [8]:
```
# We can visualize the distance matrix: each row is a single test exampl
e and
# its distances to training examples
plt.imshow(dists, interpolation='none')
plt.show()
```



Inline Question #1: Notice the structured patterns in the distance matrix, where some rows or columns are visible brighter. (Note that with the default color scheme black indicates low distances while white indicates high distances.)

- What in the data is the cause behind the distinctly bright rows?
- What causes the columns?

Your Answer: A test point far (or with high distance) from many training points causes a distinctly bright row. A training point far (or with high distance) from many test points causes the columns.

```
In [9]: dists.shape
Out[9]: (500, 5000)
```

```
In [10]: y_train.shape
Out[10]: (5000,)
```

```
In [11]: # Now implement the function predict_labels and run the code below:
         # We use k = 1 (which is Nearest Neighbor).
         y_test_pred = classifier.predict_labels(dists, k=1)

         # Compute and print the fraction of correctly predicted examples
         num_correct = np.sum(y_test_pred == y_test)
         accuracy = float(num_correct) / num_test
         print('Got %d / %d correct => accuracy: %f' % (num_correct, num_test, ac
         curacy))
```

```
Got 137 / 500 correct => accuracy: 0.274000
```

You should expect to see approximately `27%` accuracy. Now lets try out a larger `k`, say `k = 5`:

```
In [12]: y_test_pred = classifier.predict_labels(dists, k=5)
         num_correct = np.sum(y_test_pred == y_test)
         accuracy = float(num_correct) / num_test
         print('Got %d / %d correct => accuracy: %f' % (num_correct, num_test, ac
         curacy))
```

```
Got 145 / 500 correct => accuracy: 0.290000
```

You should expect to see a slightly better performance than with `k = 1`.

Inline Question 2 We can also other distance metrics such as L1 distance. The performance of a Nearest Neighbor classifier that uses L1 distance will not change if (Select all that apply.):

1. The data is preprocessed by subtracting the mean.
2. The data is preprocessed by subtracting the mean and dividing by the standard deviation.
3. The coordinate axes for the data are rotated.
4. None of the above. (Mean and standard deviation in (1) and (2) are vectors and can be different across dimensions)

Your Answer:
1 and 2.
Your explanation:
1) Let's say the the original distance is $\sum_D |x_d - y_d|$. Then after subtracting m_d (the mean of dimension d) from each point, the new distance is
$\sum_D |(x_d - m_d) - (y_d - m_d)| = \sum_D |x_d - m_d - y_d + m_d)| = \sum_D |x_d - y_d|$ = original distance. Therefore, the L1 distance will not change if the data is preprocessed by subtracting the mean.

2) Preprocessing by subtracting the mean and dividing by the standard deviation will normalize the data. The L1 distances will change, however, since from each point we subtract the mean and divide that by the same standard deviation, the relative distances will be preserved. Therefore, the performance of the KNN classifier won't be affected.

3) Rotating the coordinate axes for the data will cause the to not preserve the relative distances, and hence will affect the performance of the KNN classifier.

In [13]:
```
# Now lets speed up distance matrix computation by using partial vectori
zation
# with one loop. Implement the function compute_distances_one_loop and r
un the
# code below:
dists_one = classifier.compute_distances_one_loop(X_test)

# To ensure that our vectorized implementation is correct, we make sure
 that it
# agrees with the naive implementation. There are many ways to decide wh
ether
# two matrices are similar; one of the simplest is the Frobenius norm. I
n case
# you haven't seen it before, the Frobenius norm of two matrices is the
 square
# root of the squared sum of differences of all elements; in other word
s, reshape
# the matrices into vectors and compute the Euclidean distance between t
hem.
difference = np.linalg.norm(dists - dists_one, ord='fro')
print('Difference was: %f' % (difference, ))
if difference < 0.001:
    print('Good! The distance matrices are the same')
else:
    print('Uh-oh! The distance matrices are different')
```

```
Difference was: 0.000000
Good! The distance matrices are the same
```

In [14]:
```
# Now implement the fully vectorized version inside compute_distances_no
_loops
# and run the code
dists_two = classifier.compute_distances_no_loops(X_test)

# check that the distance matrix agrees with the one we computed before:
difference = np.linalg.norm(dists - dists_two, ord='fro')
print('Difference was: %f' % (difference, ))
if difference < 0.001:
    print('Good! The distance matrices are the same')
else:
    print('Uh-oh! The distance matrices are different')
```

```
Difference was: 0.000000
Good! The distance matrices are the same
```

In [15]:

```
# Let's compare how fast the implementations are
def time_function(f, *args):
    """
    Call a function f with args and return the time (in seconds) that it
took to execute.
    """
    import time
    tic = time.time()
    f(*args)
    toc = time.time()
    return toc - tic

two_loop_time = time_function(classifier.compute_distances_two_loops, X_
test)
print('Two loop version took %f seconds' % two_loop_time)

one_loop_time = time_function(classifier.compute_distances_one_loop, X_t
est)
print('One loop version took %f seconds' % one_loop_time)

no_loop_time = time_function(classifier.compute_distances_no_loops, X_te
st)
print('No loop version took %f seconds' % no_loop_time)

# you should see significantly faster performance with the fully vectori
zed implementation
```

```
Two loop version took 31.654346 seconds
One loop version took 45.155846 seconds
No loop version took 0.428838 seconds
```

Cross-validation

We have implemented the k-Nearest Neighbor classifier but we set the value k = 5 arbitrarily. We will now determine the best value of this hyperparameter with cross-validation.

In [16]:
```
num_folds = 5
k_choices = [1, 3, 5, 8, 10, 12, 15, 20, 50, 100]

X_train_folds = []
y_train_folds = []
########################################################################
########
# TODO:
#
# Split up the training data into folds. After splitting, X_train_folds
 and    #
# y_train_folds should each be lists of length num_folds, where
#
# y_train_folds[i] is the label vector for the points in X_train_folds
[i].     #
# Hint: Look up the numpy array_split function.
#
########################################################################
########
indexes = np.arange(len(X_train))
np.random.shuffle(indexes)
split_indexes = np.array_split(indexes, num_folds)
for i in range(num_folds):
    X_train_folds.append(X_train[split_indexes[i]])
    y_train_folds.append(y_train[split_indexes[i]])
########################################################################
########
#                                 END OF YOUR CODE
#
########################################################################
########

# A dictionary holding the accuracies for different values of k that we
 find
# when running cross-validation. After running cross-validation,
# k_to_accuracies[k] should be a list of length num_folds giving the dif
ferent
# accuracy values that we found when using that value of k.
k_to_accuracies = {}

########################################################################
########
# TODO:
#
# Perform k-fold cross validation to find the best value of k. For each
#
# possible value of k, run the k-nearest-neighbor algorithm num_folds ti
mes,   #
# where in each case you use all but one of the folds as training data a
nd the #
# last fold as a validation set. Store the accuracies for all fold and a
ll     #
# values of k in the k_to_accuracies dictionary.
#
########################################################################
```

```
########
for k in k_choices:
    accuracies = []
    for i in range(num_folds):
        train_y = np.array([])
        train_X = None
        test_y = np.array([])

curacy))
```

```
Got 147 / 500 correct => accuracy: 0.294000
```

Inline Question 3 Which of the following statements about k-Nearest Neighbor (k-NN) are true in a classification setting, and for all k? Select all that apply.

1. The training error of a 1-NN will always be better than or equal to that of 5-NN.
2. The test error of a 1-NN will always be better than that of a 5-NN.
3. The decision boundary of the k-NN classifier is linear.
4. The time needed to classify a test example with the k-NN classifier grows with the size of the training set.
5. None of the above.

Your Answer: 1, 4

Your explanation:

1. It is true because the closest point to each point would be itself (because distance of a point to itself is 0) and therefore it will always find the correct label.

2. In most cases the test error in a 5-NN classifier would be lower than a 1-NN classifier, since a 5-NN classifier will compare to more near by neighbours, hence generalizing better. However, there could be instances where sometimes a 1-NN classifier will perform better than a 5-NN classifier.

3. The decision boundary of the k-NN classifier is non-linear since the distance functions used for it are non-linear. So therefore most decision boundaries look like a curve rather than a hyperplane.

4. In KNN the distance of the test point is calculated from each training point. So therefore, as the training set gets larger the time taken to calculate the distance of the test point from all training points will get larger. Therefore, The time needed to classify a test example with the k-NN classifier grows with the size of the training set.
